

TASK RECORD

NAME: VIKASINI.K

DEPARTMENT: B. Tech CSE (Artificial Intelligence and Data Science)

COLLEGE: Vels institute of science, Technology and Advanced studies

INTERNSHIP ROLE: Data Analyst

TASK: AGILE METHODOLOGIES AND PROJECT MANAGEMENT TOOLS

Task Description:

As part of this task, I learned about Agile methodologies and some project management tools. Before learning this topic, I only had a basic idea about how projects are managed. After studying Agile, I understood that it is a way of doing a project step by step instead of trying to complete everything at the same time.

AGILE:

Agile means doing the work step by step, checking it regularly, and making changes whenever needed. I understood that Agile is very useful in software projects because the requirements may change while developing the project.

AGILE METHODOLOGIES:

There are some common Agile methodologies such as Scrum, Kanban, Extreme Programming and Lean.

- Scrum : Scrum is one of the popular Agile methodologies.
- Kanban: Kanban is a simple visual method of managing tasks.
- Lean focuses on reducing unnecessary work and saving time and resources.

JIRA:

Jira is a project management and issue-tracking tool. It is commonly used by software development teams.

Jira supports Agile methods like Scrum and Kanban

FUNCTIONS:

- Create tasks
- Assign tasks
- Track bugs
- Manage sprints
- Track project progress
- Use Scrum or Kanban boards

MS PROJECT:

MS Project is a project management software from Microsoft. It is mainly used for planning and scheduling projects. It can help a project manager manage tasks, deadlines, resources and dependencies.

EXAMPLE:

If a project has many tasks and deadlines, MS Project can help us understand which task should be completed first and how much time each task may take.

NOTION:

Notion is a workspace tool that can be used for notes, documentation and project management. We can create pages, task lists, tables, databases and boards in Notion.

USES OF NOTION ARE:

- Taking notes
- Creating to-do lists
- Managing project tasks
- Maintaining project documentation
- Creating tables
- Tracking deadlines

ASANA:

Asana is another project management tool used for managing tasks and team projects. We can create tasks, assign them to team members, set deadlines and track the progress. Asana also provides different views such as list, board, calendar and timeline.

Example:

In a college project, one person can work on documentation, another person can work on coding, and another person can work on testing. These tasks can be added to Asana and assigned to the team members.

WHAT I LEARNED FROM THIS TASK:

This task helped me understand that project management is not just about completing tasks. We also need to plan the work, divide responsibilities, track progress and communicate with the team.

DIFFICULTIES I FACED:

While learning Agile methodologies and project management tools, I faced some difficulties in understanding the concepts clearly. At first, terms like Sprint, Scrum, Kanban, User Story, and Backlog were confusing for me.

I also found it difficult to understand the difference between Jira, MS Project, Notion, and Asana, because all of them are used for project management but their features are different.

Another difficulty I faced was understanding how these tools are actually used in a real project. After studying some examples, I got a better idea about their uses.

Overall, I found the topic a little difficult at the beginning, but after learning each concept step by step, I was able to understand it better.
